Memory Corruption Bugs: Basics

Memory Corruption Bugs: Results of successful exploits

■ Denial of Service

- Induce process crash, prevent clients from accessing service

■ Information Disclosure

- Leaking private information (e.g., passwords, private keys)
- Often 1st step in circumventing mitigation techniques (e.g., leaking process space address information)

■ Control Flow Hijacking

- Maliciously alter the process' behaviour: "Arbitrary Code Execution"

Memory Corruption Bugs: Control Flow Hijacking

1. Modify control flow data / metadata with user input
 - Function return address
 - Function pointer
 - Virtual method table
 - Heap metadata
 - Global Offset Table (GOT) or Import Address Table (IAT)
2. Redirect Control Flow
 - to injected (machine) code
 - or to existing code in the process' memory space

Registers (x86):

- `%eip`: points to next instruction being executed
- `%esp`: points to end of stack

Stack: store for information about currently active subroutine

Stack Layout: Before Function Call

```
1 void gray ()
2 {
3     ...
4     yellow(a1, a2);
5     ...
6 }
7
8 int yellow(int p1, int p2)
9 {
10     char buf[3];
11     int l1, l2;
12
13     l2 = blue(l1, buf);
14     return l2;
15 }
```

- Function `gray` pushes parameters for function `yellow` on the stack

Stack Layout: During Function Call

```
1 void gray ()
2 {
3     ...
4     yellow(a1, a2);
5     ...
6 }
7
8 int yellow(int p1, int p2)
9 {
10     char buf[3];
11     int l1, l2;
12
13     l2 = blue(l1, buf);
14     return l2;
15 }
```

- Call instruction pushes %eip register (return address) on the stack

Stack Layout: Function Prologue

```
1 void gray ()
2 {
3     ...
4     yellow(a1, a2);
5     ...
6 }
7
8 int yellow(int p1, int p2)
9 {
10     char buf[3];
11     int l1, l2;
12
13     l2 = blue(l1, buf);
14     return l2;
15 }
```

- Save gray's frame pointer (%ebp)
- Update frame pointer
- Save callee-saved registers

Stack Layout: Function Prologue

```
1 void gray()  
2 {  
3     ...  
4     yellow(a1, a2);  
5     ...  
6 }  
7  
8 int yellow(int p1, int p2)  
9 {  
10  char buf[3];  
11  int l1, l2;  
12  
13  l2 = blue(l1, buf);  
14  return l2;  
15 }
```

- Allocate local variables

Stack Layout: Function Prologue

```
1 void gray()  
2 {  
3     ...  
4     yellow(a1, a2);  
5     ...  
6 }  
7  
8 int yellow(int p1, int p2)  
9 {  
10     char buf[3];  
11     int l1, l2;  
12  
13     l2 = blue(l1, buf);  
14     return l2;  
15 }
```

- Local Variables allocated traditionally in order of declaration

Stack Layout: Before Function Call

```
1 void gray()  
2 {  
3     ...  
4     yellow(a1, a2);  
5     ...  
6 }  
7  
8 int yellow(int p1, int p2)  
9 {  
10     char buf[3];  
11     int l1, l2;  
12  
13     l2 = blue(l1, buf);  
14     return l2;  
15 }
```

- Save caller-saved registers
- Push params for blue

Stack Layout: During Function Call

```
1 void gray()  
2 {  
3     ...  
4     yellow(a1, a2);  
5     ...  
6 }  
7  
8 int yellow(int p1, int p2)  
9 {  
10     char buf[3];  
11     int l1, l2;  
12  
13     l2 = blue(l1, buf);  
14     return l2;  
15 }
```

Stack Layout: After Function Call

```
1 void gray()  
2 {  
3     ...  
4     yellow(a1, a2);  
5     ...  
6 }  
7  
8 int yellow(int p1, int p2)  
9 {  
10     char buf[3];  
11     int l1, l2;  
12  
13     l2 = blue(l1, buf);  
14     return l2;  
15 }
```

- Stack frame for blue and params have already been freed (by incrementing %esp)

Stack Layout: Function Epilog

```
1 void gray ()
2 {
3     ...
4     yellow(a1, a2);
5     ...
6 }
7
8 int yellow(int p1, int p2)
9 {
10     char buf[3];
11     int l1, l2;
12
13     l2 = blue(l1, buf);
14     return l2;
15 }
```

- Callee-saved registers of gray restored
- Frame pointer of gray restored
- Return address on stack will be loaded into %eip ...

Stack Layout: After Function Call

```
1 void gray ()
2 {
3     ...
4     yellow(a1, a2);
5     ...
6 }
7
8 int yellow(int p1, int p2)
9 {
10     char buf[3];
11     int l1, l2;
12
13     l2 = blue(l1, buf);
14     return l2;
15 }
```

stack frame of
gray

- ... and execution continues right after the call to yellow in function gray

Stack Layout: Purpose of Frame Pointer

```
1 void gray()  
2 {  
3     ...  
4     yellow(a1, a2);  
5     ...  
6 }  
7  
8 int yellow(int p1, int p2)  
9 {  
10     char buf[3];  
11     int l1, l2;  
12  
13     l2 = blue(l1, buf);  
14     return l2;  
15 }
```

- Positive offset added to `%ebp` to address parameter
- Negative offset added to `%ebp` to address local variable

Stack Layout: Frame Pointer

```
1 void gray()  
2 {  
3     ...  
4     yellow(a1, a2);  
5     ...  
6 }  
7  
8 int yellow(int p1, int p2)  
9 {  
10     char buf[3];  
11     int l1, l2;  
12  
13     l2 = blue(l1, buf);  
14     return l2;  
15 }
```

- `%ebp` can often be optimized away
- gcc: `-fomit-frame-pointer`

Stack Buffer Overflow: Vulnerable Program

```
1 int main(int argc, char** argv)
2 {
3     char val;
4     val = yellow(5, argv[1]);
5     printf("auth: %c", val);
6 }
7
8 int yellow(int len, char* text)
9 {
10    char authenticated = 'N';
11    char buf[3];
12    ...
13    strcpy(buf, text);
14    ...
15    return authenticated;
16 }
```

Stack Buffer Overflow: Local Variable Spill

```

$ gcc -fno-stack-protector -g -o vuln vuln.c
$ ./vuln 1
authenticated: Y
$ ./vuln 123
authenticated: N
$ ./vuln 123Y
authenticated: Y

```

- buf[3] overflows with user input "123Y"
- "Y" spills into variable authenticated

Stack Buffer Overflow: Disrupt Control Flow

What if we spill input further up the stack?

- Return address gets overwritten
- Program segfaults after function yellow tries to return

```
$ gcc -fno-stack-protector -g -o vuln vuln.c
$ ./vuln 123YAAAAAAAAAAAAAAAAAAAA
Segmentation fault
$
```

Stack Buffer Overflow: Stack Content Before Overflow

Stack content right before call to strcpy

- At 0xbffff36c the char array buf starts
- At 0xbffff37c the original return address is stored
- At 0xbffff378 the frame pointer of main is stored

```
gdb$ run AAAABBBBCCCCDDDDDEEEE
Breakpoint 1, 0x080484dd in yellow (len=0x5, text=0xbffff5e9 "AAAABBBBCCCCDDDDDEEEE") at vuln.c:17
17      strcpy(buf, text);
gdb$ x/12x buf
0xbffff36c:  0x4e048354  0xb7ff1080  0x08049ff4  0xbffff3a8
0xbffff37c:  0x080484a5  0x00000005  0xbffff5e9  0x08048520
0xbffff38c:  0xbffff3a8  0xb7e91235  0xb7ff1080  0x0804852b
```

Stack Buffer Overflow: Stack Content After Overflow

Stack content right after call to strcpy

- buf is filled with the string "AAA" (ascii code for 'A': 0x41)
- The rest of the input string "AAAABBBBCCCCDDDDDEEEEE" overflows
- The original return address at 0xbffff37c is overwritten with 0x45454545

```
gdb$ nexti
18      return authenticated;
gdb$ x/12x buf
0xbffff36c:  0x41414141  0x42424242  0x43434343  0x44444444
0xbffff37c:  0x45454545  0x00000000  0xbffff5e9  0x08048520
0xbffff38c:  0xbffff3a8  0xb7e91235  0xb7ff1080  0x0804852b
```

Stack Buffer Overflow: Redirect Control Flow

We can redirect control flow to (almost) arbitrary locations in the process' memory space.

```
$ gdb -q ./vuln
gdb$ run `./msf4/tools/pattern_create.rb 64`
Program received signal SIGSEGV, Segmentation fault.

Cannot access memory at address 0x61413561
0x61413561 in ?? ()
gdb$ info function hello
All functions matching regular expression "hello":

File vuln.c:
void hello world();
gdb$ p &hello_world
$1 = (void (*)()) 0x80484e8 <hello_world>
gdb$ q

$ ./msf4/tools/pattern_offset.rb 61413561
16

$ ./vuln `perl -e 'print "A"x16'` printf '\xe8\x84\x04\x08'
Hello - I am an unreachable function

$
```

Stack Buffer Overflow: Arbitrary Code Execution

Inject own malicious code
(“shellcode”) into the process’
memory space:

- Provide the shellcode as part of the input string, it gets copied in the buffer buf
- Overwrite return address to point to the beginning of buf [3]

Achieved: arbitrary
attacker-controlled computations.

Stack Buffer Overflow Attack: Summary

- Fill buffer with own code (shellcode)
- Overwrite return address
- Return address points to shellcode
- When leaving the current function
 - Overwritten return address will be loaded into %eip register (instruction pointer)
 - %eip register points to shellcode
 - Shellcode will be executed

Stack Buffer Overflow: Recapitulation

Basic stack layout, a horizontal perspective

Stack Buffer Overflow: Recapitulation

String spills out of buffer, overwrites saved return address.

Stack Buffer Overflow: NOP-Sled

New return address needs to point to buffer: Exact location not known.

- Prepend **NOP-Sled** to shellcode as “landing zone”
- Make an educated guess for an address somewhere in the NOP-Sled
